

## Digital Signal Processing with the PIC16C74

Author: *Darius Mostowfi*  
*Design Consultant*

### INTRODUCTION

The use of general purpose microcontrollers for low-end digital signal processing applications has become more commonplace these days with the availability of higher speed processors. Since most signal processing systems consist of a host processor and dedicated DSP chip, the use of a single microcontroller to perform both these functions provides a simpler and lower cost solution. In addition, the single chip design will consume less power which is ideal for battery powered applications. The PIC16C74 with its on-chip A/D, PWM module, and fast CPU is an ideal candidate for use in these low-bandwidth signal processing applications.

A typical signal processing system includes an A/D converter, D/A converter, and CPU that performs the signal processing algorithm as shown in Figure 1.

The input signal,  $x(t)$ , is first passed through an input filter (commonly called the anti-aliasing filter) whose function is to bandlimit the signal to below the Nyquist rate (one half the sampling frequency) to prevent aliasing. The signal is then digitized by the A/D converter at a rate determined by the sample clock to produce  $x(n)$ , the discrete-time input sequence. The system transfer function,  $H(z)$ , is typically implemented in the time-domain using a difference equation. The

output sample,  $y(n)$ , is then converted back into the continuous-time signal,  $y(t)$ , by the D/A converter and output low-pass filter.

The calculation of the output signal using a difference equation requires a multiply and accumulate (MAC) operation. This is typically a single-cycle instruction on DSP chips but can take many cycles to perform on a standard microcontroller since it must be implemented in code. Since the digitization of the signal, calculation of the output, and output to the D/A converter all must be completed within the sample clock period, the speed at which this can be done determines the maximum bandwidth that can be achieved with the system. The relatively slow speed of most microcontrollers is the major limitation when they are used in DSP applications but the PIC16C74's fast instruction execution speed (as fast as 200 ns/instruction) can provide the performance required to implement relatively low bandwidth systems. In addition, the device's on-chip A/D and PWM modules provide all the functions needed for a single chip system. Only a few external components are needed to use the PIC16C74 for tone generation, filtering of transducer signals, or low bandwidth control.

This application note describes the basic issues that need to be addressed in order to implement digital signal processing systems using the PIC16C74 and provides application code modules and examples for DTMF tone generation, a 60 Hz notch filter, and a simple PID compensator for control systems. These routines can also be used with other PIC16C6X and PIC16C7X processors with minor modifications and the addition of external analog I/O devices.

**FIGURE 1: TYPICAL SIGNAL PROCESSING SYSTEM**

## CODE DEVELOPMENT TOOLS

The code for these applications was written using Byte Craft's MPC C compiler. The MPC compiler provides an Integrated Development Environment (IDE) and generates highly optimized code for the entire PIC16CXX/17CXX family. For new PIC16CXX/17CXX users that are familiar with C, this is an ideal way to quickly develop code for these processors. In addition, the listing files can be studied in order to learn the details of PIC16CXX/17CXX assembly language. The modules and examples for this application note use C for the main program body and in-line assembly language for the time-critical routines. MPC provides interrupt support so that interrupt service routines (ISRs) can be easily written in either C or assembly. This feature was used to provide a timer ISR for one of the code modules. The compiler proved to be a valuable tool that allowed both high level and assembly language routines to be written and tested quickly.

In order to provide the double precision math functions required for this application note, a couple of existing math functions written for the PIC16C54 (see AN525) were converted for use with MPC. The double precision multiply and addition routines were modified by first changing all RAM declarations done in EQU statements to C "unsigned char" variable declarations. The main body of assembly language code was preceded by "#asm" and ended by "#endasm" preprocessor directives which tell the compiler where the in-line assembly code starts and ends. Finally, any macro sections and register names that are defined differently in MPC were changed.

The assembly language routines for tone generation and filtering were also written as C functions using the compiler. Assembly language routines written in this way can be called directly from other assembly language modules or called directly from C by using the label name as a C function. Source listings for all the modules and example programs can be found in the appendices at the end of this application note. These modules can be directly compiled using the MPC compiler or, alternatively, the assembly language sections can be used with MPASM with minor modifications.

### Number Representation and Math Routines

One of the challenges of using any general purpose microcontroller for signal processing algorithms is in implementing the finite word-length arithmetic required to perform the calculations. As mentioned before, the speed at which the MAC operations can be performed limits the maximum achievable bandwidth of the system. Therefore, the routines that perform the multiplication and the main signal processing algorithms need to be optimized for speed in order to obtain the highest possible bandwidth when using the PIC16C74.

The selection of word size and coefficient scaling are also important factors in the successful implementation of signal processing systems. The effects of using a fixed word length to represent the signal and do calculations fall into three categories: signal quantization, round-off error, and coefficient quantization. The signal quantization due to the A/D converter and round-off error due to the finite precision arithmetic affect the overall signal-to-noise performance of the system. Scaling of the input signal should be done before the A/D converter to use the full input range and maximize the input signal-to-noise ratio. The use of double precision math for all calculations and storing intermediate results, even if the input and output signals are represented as 8-bit words, will help to reduce the round-off error noise to acceptable levels. Coefficient quantization occurs when the calculated coefficients are truncated or rounded off to fit within the given word length. This has the effect of moving the system transfer function poles and zeros which can change the system gain, critical frequencies of filters, or stability of the system. The successful implementation of these systems requires careful design and modeling of these effects using one of the many software programs that are available. The code written for this application note was first modeled using PC MATLAB before being implemented on the PIC16C74.

The algorithms in this application note are all implemented using fixed point two's complement arithmetic. Two math libraries were used for the examples: one 8-bit signed multiply routine that was written specifically for the tone generation algorithm, and the modified double precision routines for the PIC16C54 that were used in the filtering routine. All numbers are stored in fractional two's complement format where the MSB is the sign bit and there is an implied decimal point right after it. This is commonly referred to as Qx format where the number after the Q represents the number of fractional bits in the word. For instance, 16 bit words with the decimal point after the MSB would be referred to as Q15. This format allows numbers over the range of -1 to 0.99 to be represented and, because the magnitude of all numbers is less than or equal to one, has the advantage that there can be no overflow from a multiplication operation.

Since calculations are done using two's complement arithmetic, values read by the PIC16C74's A/D converter need to be converted to this format. This can be easily done if the input is set up to read values in offset binary format. In this representation, the most negative input voltage is assigned to the number 0, zero volts is assigned the number 128, and the most positive voltage input is assigned 255. Since the PIC16C74 has a unipolar input A/D converter, a bipolar input signal must be scaled to be between 0 and 5V. One way to accomplish this is to use an op-amp scaling and offset circuit. The signal should be centered at 2.5V and have a peak to peak voltage swing of

4 to 4.5V. The offset binary number can be converted to two's complement format by simply complementing the MSB of the word. Once the signal processing calculations are completed, the number can be converted back to offset binary by complementing the MSB before it is written to the PWM module. A similar level shifting circuit can be used at the PWM output to restore the DC level of the signal. Using this technique allows a wide range of analog input voltages to be handled by the PIC16C74.

## A/D and D/A Conversion

The PIC16C74's internal 8-bit A/D converter and PWM modules can be used to implement analog I/O for the system. The A/D converter along with an external anti-aliasing filter provides the analog input for the system. Depending on the input signal bandwidth and the sampling frequency, the filter can be a simple single pole RC filter or a multiple pole active filter. The PWM output along with an external output "smoothing" filter provides the D/A output for the system. This can be a simple RC filter if the PWM frequency is much higher (five to ten times) than the analog signal that is being output. Alternatively, an active filter can also be used at the PWM output. Since the use of the A/D and PWM modules is covered in detail in the data sheet for the part, they will not be covered here. In addition, since the PIC16C74's A/D converter is similar to the PIC16C71 and the PWM module is the same as the PIC16C74, the use of these is also covered in application notes AN546, AN538, and AN539.

Appendix A contains the listing for the C module "ANALOGIO.C" that has the functions that read the A/D converter input, initialize the PWM module, and write 8-bit values to the PWM module. The number format (offset binary or two's complement) for the A/D and PWM values as well as the PWM resolution and mode are set using "#define" pragmas at the beginning of the module. The get\_sample() function takes the A/D input multiplexer channel number as an argument and returns the measured input value. The init\_PWM() function takes the PWM period register PR2 value as an argument. The write\_PWM() function takes the output values for PWM module 1 and 2 and writes them to the appropriate registers using the specified resolution. If the second argument to the function is 0, the registers for PWM module 2 are unaffected. The PWM resolution is always 8-bits but the mode used depends on the PWM frequency.

The A/D conversions need to be performed at the system sample rate which requires that some form of sample clock be generated internally or input from an external source. One way to generate this clock internally, in software with minimal effort, is to use the Timer2 interrupt. Since Timer2 is used to generate the PWM period, enabling the Timer2 interrupt and using the Timer2 postscaler can generate an interrupt at periods that are integer divisors of the PWM period. The ISR can set a software "sample flag" that is checked by the main routine. Once the sample flag is

asserted by the ISR, the main routine can then clear it and perform the signal processing operation, output the next sample, and then wait for the sample flag to be asserted true again. Alternatively, a separate timer/counter or external clock input can be used for the system sample clock. The latter two methods have the advantage that the PWM frequency can be set independent of the sampling period. For best results, the PWM frequency should be set for at least five times the maximum frequency of the analog signal that is being reproduced. The example programs illustrate the use of both of the methods for generating an internal sample clock.

## Tone Generation

For systems that need to provide audible feedback or to provide DTMF signaling for telcom applications, the PIC16C74's PWM module can be used to generate these signals. One way to do this is to output samples of a sinusoidal waveform to the PWM module at the system sampling rate. This method is relatively simple but is limited to single tones and may require large amounts of memory depending on the number of samples used per cycle of the waveform and the number of tones that need to be generated. A more efficient method of generating both single and dual-tone signals is to use a difference equation method. This method uses a difference equation that is derived from the z-transform of a sinusoid as follows:

The z-transform of a sinusoid is

$$\frac{z^{-1}\sin\omega T}{1 - 2z^{-1}\cos\omega T + z^{-2}}$$

where the period  $\omega = 2\pi f$  and T is the sampling period.

If this is interpreted as the transfer function  $H(z) = Y(z)/X(z)$  then the difference equation can be found taking the inverse z-transform and applying the associated shift theorem as follows:

rearranging:

$$Y(z)(1 - 2z^{-1}\cos\omega T + z^{-2}) = X(z)(z^{-1}\sin\omega T)$$

$$Y(z) = z^{-1}X(z)\sin\omega T + z^{-1}Y(z)2\cos\omega T - z^{-2}Y(z)$$

taking the inverse z-transform:

$$Z^{-1}[Y(z)] = Z^{-1}[z^{-1}X(z)\sin\omega T + z^{-1}Y(z)2\cos\omega T - z^{-2}Y(z)]$$

$$y(n) = \sin\omega T x(n - 1) + 2\cos\omega T y(n - 1) - y(n - 2)$$

If we let  $a = \sin\omega T$  and  $b = \cos\omega T$ , the equation can be written as:

$$y(n) = a x(n - 1) + 2b y(n - 1) - y(n - 2)$$

# AN616

thus we have a difference equation with coefficients  $a$  and  $b$ . Note that only two coefficients are needed to generate a sinusoidal output sequence. These are calculated from the relationship above and stored in memory for use by the tone generation algorithm.

If we input an impulse to this system ( $x(n) = 1$  at  $n = 0$  and is zero elsewhere) then the output of the system will be a discrete-time sinusoidal sequence. Note that at  $n = 0$ , the output will always be 0 and  $x(n)$  is only 1 at  $n = 1$  so the sequence becomes:

$$\begin{aligned}y(0) &= 0 \\y(1) &= a \\y(n) &= 2b y(n - 1) - y(n - 2) \\&\text{for } n \text{ equal to or greater than } 2\end{aligned}$$

In order to further simplify the implementation of the algorithm, we can omit the first sample period. Since the output is already at 0 before starting, this will make no difference in the final output other than the fact that it will be time shifted by one sample. To generate dual tones, the algorithm is executed once for each tone and the two output samples are summed together. Since the output must be calculated and output to the D/A each sample period, a limitation exists on the frequency of the tone that can be produced for a given sample rate and processor speed. The higher the ratio of the sample clock to the tone frequency, the better, but a sample rate of at least three to four times the highest tone output should produce a sine wave with acceptable distortion.

Appendix B contains the listing for the "PICTONE.C" module which uses the difference equation method to produce variable length tones from the PWM module. Timer2 is used to generate the PWM period as well as the sample clock and tone duration timer. To send a tone, the coefficients and duration are written to the appropriate variables and then the tone routine is called. If the  $a2$  and  $b2$  coefficients are cleared, the routine will only generate a single tone sequence. The difference equation algorithm uses 8-bit signed math routines for the multiply operations. Using 8-bit coefficients reduces the accuracy by which the tones can be generated but greatly reduces the number of processor cycles needed to perform the algorithm since only single precision arithmetic is used. The spectrum of a single tone signal generated using this routine is shown in Figure 2.

Note that the second harmonic is better than 40 dB below the fundamental. Accuracy of this particular tone is better than 0.5%.

An example program "DTMFGEN.C" illustrates the use of the tone module to generate the 16 standard DTMF tones used for dialing on the telephone system. A sampling rate of 6.5 kHz was used which allows dual tones to be generated on a processor running at 10 MHz. Accuracy with respect to the standard DTMF frequencies is better than 1% for all tones and all harmonics above the fundamental frequency are greater than 30 dB down.

**FIGURE 2: SINGLE TONE SIGNAL**

## Digital Filters

Digital filters with critical frequencies up to a kilohertz or so can be implemented on the PIC16C74. Digital filters fall into two classes: Finite Impulse Response (FIR) and Infinite Impulse Response (IIR) filters. FIR filters require more coefficients and multiplication operations to implement practical filters and are not as well suited for implementation on the PIC16C74. IIR type filters are typically designed starting with an analog filter prototype and then performing an analog to digital transformation to produce the digital filter coefficients. The subject of digital filter design is not within the scope of this application note but there are many excellent texts that cover the theory and design of these filters.

The implementation of a second-order IIR filter is done by using a second-order difference equation. A second-order infinite impulse response (IIR) filter has a transfer function of the form:

$$H(z) = \frac{b_0 + b_1z^{-1} + b_2z^{-2}}{1 + a_1z^{-1} + a_2z^{-2}}$$

Where  $a_1$ ,  $a_2$ ,  $b_0$ ,  $b_1$ , and  $b_2$  are the coefficients of the polynomials of the system transfer function that, when factored, yield the system poles and zeros. The difference equation found by taking the inverse z-transform and applying the shift theorem is:

$$y(n) = b_0x(n) + b_1x(n-1) + b_2x(n-2) - a_1y(n-1) - a_2y(n-2)$$

Since the transfer function coefficients are used directly in the difference equation, this is often called the "Direct Form I" implementation of a digital filter. This form has its limitations due to numerical accuracy issues but is effective for implementing second-order systems.

Appendix C contains the listing for the general-purpose filter routine "IIR\_FILT.C" that can be used to implement low-pass, high-pass, bandpass, and bandstop (notch) filters. The filter() function takes an 8-bit input value  $x(n)$  and calculates the output value  $y(n)$ . The filter coefficients are stored as 16-bit two's complement numbers and computation of the output is done using double precision arithmetic. Since the coefficients generated from the filter design program will be in decimal form, they need to be scaled to be less than 1 and then multiplied by 32,768 to put them in Q15 format. Additional scaling by factors of two may be required to prevent overflow of the sum during calculations. If this is done, the output must be multiplied by this scale factor to account for this. The "IIR\_FILT.C" module contains two other subroutines required for the filtering program. One of these is a decimal adjust subroutine to restore the decimal place after two 16-bit Q15 numbers are multiplied. The subroutine shifts the 32-bit result left by one to get rid of the extra sign bit.

The other routine scales the output by factors of two and is used after the output of the filter has been calculated to account for the scaling of the coefficients.

An example program "NOTCH\_60.C" is provided that illustrates the implementation of a 60 Hz notch filter using the "IIR\_FILT.C" module. The filter was modeled and designed using PC MATLAB before being implemented on the PIC16C74. A sample rate of 1 kHz is used which means that signals up to a few hundred hertz can be processed. The filter provides an attenuation of about 40 dB at 60 Hz and can be used to remove interference from sensor signals in a system.

## Digital Control

A low bandwidth digital control system can be implemented on the PIC16C74 using the analog I/O and IIR filter routines. A typical digital control system is shown below:

**FIGURE 3: TYPICAL DIGITAL CONTROL SYSTEM**

The input,  $r$ , is the reference input and  $y(t)$  is the continuous-time output of the system.  $G(s)$  is the analog transfer function of the plant (controlled system) and  $K(z)$  is the digital compensator. The error signal is calculated by subtracting the measured output signal,  $y(n)$ , from the reference. The controller transfer function is essentially a filter that is implemented in the time-domain using a difference equation. Since digital control system design is a complex subject and the design of a suitable compensator depends on the system being controlled and the performance specifications, only the implementation issues will be discussed.

One popular and well understood compensator is the Proportional-Integral-Derivative (PID) controller whose transfer function is of the form:

$$K(z) = K_P + \frac{K_I}{1 - z^{-1}} + K_D(1 - z^{-1})$$

Where  $K_P$  is the proportional gain,  $K_I$  is the integral gain, and  $K_D$  is the derivative gain. The transfer function can be implemented directly or can be put in the form of a standard second-order difference equation from the modified transfer function as shown below:

$$H(z) = \frac{(K_I T^2 + K_P T + K_D) - (2K_D + K_P T)z^{-1} + K_D z^{-2}}{T(1 - z^{-1})}$$

$$y(n) = (K_P + K_I T + \frac{K_D}{T})x(n) - (K_P + \frac{2K_D}{T})x(n - 1) + \frac{K_D}{T} x(n - 2) - y(n - 1)$$

Since the numerator coefficients will be greater than one, a gain factor  $K$  needs to be factored out so that the resulting coefficients are less than one. In this way, the IIR filter routine can be used to implement the controller. After the filter routine, the output  $y$  needs to be multiplied by  $K$  before being output to the PWM module. Since the gain can be high, this result needs to be checked for overflow and limited to the maximum 8-bit value, if required. Saturating the final result prevents the system from going unstable if overflow in the math does occur. The gains can also be applied externally at the D/A output. For example, the PWM can drive a power op-amp driver that provides a +/- 20 volt swing for a DC motor.

## RESULTS AND CONCLUSION

The results obtained using the PIC16C74 in these applications were impressive. The tone generation routines produce very clean sinusoidal signals and DTMF tones generated using this routine have been used to dial numbers over the telephone system with excellent results. In addition, tones used for audible feedback are more pleasing to the ear than those generated from a port pin as is typically done on processors without PWM modules. Using the PIC16C74 to generate these tones eliminates the need for special DTMF generator IC's thus reducing the cost and simplifying the design. The tone routine requires approximately 125 instruction cycles to calculate an output sample for a single tone output and 230 instruction cycles to calculate an output sample for a dual tone output.

The IIR filtering routines produce good results and have been used to filter 60 Hz signals on sensor lines and also to implement a simple PID controller system with excellent results. The IIR routine takes approximately 1670 instruction cycles to calculate the output. Table 1 shows the performance that can be expected with the PIC16C74 for various processor speeds.

In conclusion, the PIC16C74 provides the necessary performance to provide these simple, low bandwidth signal processing operations. This means that products using this device can benefit from cost and power savings by eliminating specialized components that normally perform these tasks.

## APPENDIX B: TONE GENERATION MODULE

```
/******  
* Tone Generation Module  
*  
* Written for "Digital Signal Processing with the PIC16C74" Application Note.  
*  
* This module contains a C callable module that generates single or dual  
* tones using a difference equation method:  
*  
*  $y_1(n) = a_1 * x(n-1) + b_1 * y_1(n-1) - y_1(n-2)$   
*  $y_2(n) = a_2 * x(n-1) + b_2 * y_2(n-1) - y_2(n-2)$   
*  
* The routine is written in assembly language and uses the optimized signed  
* 8x8 multiply routine and scaling routine in the file 8BITMATH.C.  
*  
* D. Mostowfi 2/95  
*****/  
#include "\mpc\apnotes\8bitmath.c" /* 8 bit signed math routines */

## APPENDIX E: NOTCH FILTER

```

/*****
* 60 Hertz Notch Filter
*
* Written for "Digital Signal Processing with the PIC16C74" Application Note.
*
* This example program use the filter() function to implement a 60Hz notch
* filter. T0 is used to generate a 1kHz sample clock. The program samples the
* input signal x(n) on A-D channel 1, calls the filter routine signal, and
* outputs y(n) to PWM channel 1.
*
* If FILTER set to 0, performs straight talkthru from A-D to PWM output.
* T0 period can be changed to cary the sample rate.
*
* D. Mostowfi 4/95

## APPENDIX G: DOUBLE PRECISION MATH ROUTINES

```

/*****
* Double Precision Math Routines
*
* This module contains assembly language routines from "Math Routines for the
* 16C5x" from Microchip's Embedded Controller Handbook that have been adapted
* for use with the Bytecraft MPC C Compiler.
*
* Routines are used IIR_FILT.C module written for "Digital Signal Processing
* with the PIC16C74" Application Note.
*
* D. Mostowfi 3/95
*****/

/*
